#### Abstract

We compute the number of symmetric $r$-colorings and the number of equivalence classes of symmetric $r$-colorings of the dihedral group $D_{p}$, where $p$ is prime.

Keywords: Dihedral group, symmetric coloring, optimal partition, Möbius function, lattice of subgroups

## 1 Introduction

The symmetries on a group $G$ are the mappings $G \ni x \mapsto$ $g x^{-1} g \in G$, where $g \in G$. This is an old notion, which can be found in the book [4]. It has also interesting relations to Ramsey theory and to enumerative combinatorics [2], [7].

Let $G$ be a finite group and let $r \in \mathbb{N}$. An $r$-coloring of $G$ is any mapping $\chi: G \rightarrow\{1, \ldots, r\}$. The group $G$ naturally acts on the colorings. For every coloring $\chi$ and $g \in G$, the coloring $\chi g$ is defined by

$$
\chi g(x)=\chi\left(x g^{-1}\right)
$$

Let $[\chi]$ and $\operatorname{St}(\chi)$ denote the orbit and the stabilizer of a coloring $\chi$, that is,

$$
[\chi]=\{\chi g: g \in G\} \text { and } S t(\chi)=\{g \in G: \chi g=\chi\}
$$

As in the general case of an action, we have that

$$
|[\chi]|=|G: S t(\chi)| \text { and } S t(\chi g)=g^{-1} S t(\chi) g
$$

Let $\sim$ denote the equivalence on the colorings corresponding to the partition into orbits, that is, $\chi \sim \varphi$ if and only if there exists $g \in G$ such that $\chi\left(x g^{-1}\right)=\varphi(x)$ for all $x \in G$.

Obviously, the number of all $r$-colorings of $G$ is $r^{|G|}$. Applying Burnside's Lemma [1, I, §3] shows that the
number of equivalence classes of $r$-colorings of $G$ is equal to

$$
\frac{1}{|G|} \sum_{g \in G} r^{|G:\langle g\rangle|}
$$

where $\langle g\rangle$ is the subgroup generated by $g$.
A coloring $\chi$ of $G$ is symmetric if there exists $g \in G$ such that

$$
\chi\left(g x^{-1} g\right)=\chi(x)
$$

for all $x \in G$. That is, if it is invariant under some symmetry. A coloring equivalent to a symmetric one is also symmetric (see [6, Lemma 2.1]). Let $S_{r}(G)$ denote the set of all symmetric $r$-colorings of $G$.

Theorem 1.[5, Theorem 1] Let $G$ be a finite Abelian group. Then

$$
\begin{aligned}
& \left|S_{r}(G)\right|=\sum_{X \leq G} \sum_{Y \leq X} \frac{\mu(Y, X)|G / Y|}{|B(G / Y)|} r r^{\frac{|G / X|+|B(G / X)|}{2}}, \\
& \left|S_{r}(G) / \sim\right|=\sum_{X \leq G} \sum_{Y \leq X} \frac{\mu(Y, X)}{|B(G / Y)|} r^{\frac{|G / X|+|B(G / X)|}{2}}
\end{aligned}
$$

Here, $X$ runs over subgroups of $G, Y$ over subgroups of $X, \mu(Y, X)$ is the Möbius function on the lattice of subgroups of $G$, and $B(G)=\left\{x \in G: x^{2}=e\right\}$.

[^0]Given a finite partially ordered set, the Möbius function is defined as follows:

$$
\mu(a, b)= \begin{cases}1 & \text { if } a=b \\ -\sum_{a<z \leq b} \mu(z, b) & \text { if } a<b \\ 0 & \text { otherwise }\end{cases}
$$

See [1, IV] for more information about the Möbius function.

In the case of $\mathbb{Z}_{n}$ these formulas can be reduced to elementary ones.

Theorem 2.[5, Theorem 2] If $n$ is odd then

$$
\begin{gathered}
\left|S_{r}\left(\mathbb{Z}_{n}\right) / \sim\right|=r^{\frac{n+1}{2}}, \\
\left|S_{r}\left(\mathbb{Z}_{n}\right)\right|=\sum_{d \mid n} d \prod_{p \left\lvert\, \frac{n}{d}\right.}(1-p) r^{\frac{d+1}{2}} .
\end{gathered}
$$

If $n=2^{l} m$, where $l \geq 1$ and $m$ is odd, then

$$
\begin{gathered}
\left|S_{r}\left(\mathbb{Z}_{n}\right) / \sim\right|=\frac{r^{\frac{n}{2}+1}+r^{\frac{m+1}{2}}}{2}, \\
\left|S_{r}\left(\mathbb{Z}_{n}\right)\right|=\sum_{d \left\lvert\, \frac{n}{2}\right.} d \prod_{p \left\lvert\, \frac{n}{2 d}\right.}(1-p) r^{d+1}
\end{gathered}
$$

In the products $p$ takes on values of prime divisors.
In this note by constructing the partially ordered set of optimal partitions we compute explicitly the number $\left|S_{r}\left(D_{p}\right)\right|$ of symmetric $r$-colorings of $D_{p}$ and the number $\left|S_{r}\left(D_{p}\right)\right| \sim \mid$ of equivalence classes of symmetric $r$-colorings of the dihedral group $D_{p}$, where $p>2$ is prime. This generalises the result from [3]. Since $D_{2}=\mathbb{Z}_{2} \oplus \mathbb{Z}_{2}$, every coloring of $D_{2}$ is symmetric, and so

$$
\left|S_{r}\left(D_{2}\right)\right|=r^{4} \text { and }\left|S_{r}\left(D_{2}\right) / \sim\right|=\frac{1}{4} r^{4}+\frac{3}{4} r^{2}
$$

## 2 Optimal partitions of $D_{p}$

In [6], Theorem 1 was generalized to an arbitrary finite group $G$. The approach is based on constructing the partially ordered set of so called optimal partitions of $G$.

Given a partition $\pi$ of $G$, the stabilizer and the center of $\pi$ are defined by
$S t(\pi)=\left\{g \in G:\right.$ for every $x \in G, x$ and $x^{-1}$
belong to the same cell of $\pi\}$,
$Z(\pi)=\left\{g \in G:\right.$ for every $x \in G, x$ and $g x^{-1} g$
belong to the same cell of $\pi\}$.
$S t(\pi)$ is a subgroup of $G$ and $Z(\pi)$ is a union of left cosets of $G$ modulo $S t(\pi)$. Furthermore, if $e \in Z(\pi)$, then $Z(\pi)$ is also a union of right cosets of $G$ modulo $\operatorname{St}(\pi)$ and for every $a \in Z(\pi),\langle a\rangle \subseteq Z(\pi)$. We say that a partition $\pi$ of $G$ is optimal if $e \in Z(\pi)$ and for every partition $\pi^{\prime}$ of $G$ with $\operatorname{St}\left(\pi^{\prime}\right)=\operatorname{St}(\pi)$ and $Z\left(\pi^{\prime}\right)=Z(\pi)$, one has $\pi \leq \pi^{\prime}$. The latter means that every cell of $\pi$ is contained in some cell of $\pi^{\prime}$, or equivalently, the equivalence corresponding
to $\pi$ is contained in that of $\pi^{\prime}$. The partially ordered set of optimal partitions of $G$ can be naturally identified with the partially ordered set of pairs $(A, B)$ of subsets of $G$ such that $A=\operatorname{St}(\pi)$ and $B=Z(\pi)$ for some partition $\pi$ of $G$ with $e \in Z(\pi)$. For every partition $\pi$, we write $|\pi|$ to denote the number of cells of $\pi$.

Theorem 3.[6, Theorem 2.11] Let $P$ be the partially ordered set of optimal partitions of $G$. Then

$$
\left|S_{r}(G)\right|=|G| \sum_{x \in P} \sum_{y \leq x} \frac{\mu(y, x)}{|Z(y)|} r^{|x|},
$$

$$
\left|S_{r}(G) / \sim\right|=\sum_{x \in P} \sum_{y \leq x} \frac{\mu(y, x)|S t(y)|}{|Z(y)|} r^{|x|}
$$

The partially ordered set of optimal partitions $\pi$ of $G$ together with parameters $|S t(\pi)|,|Z(\pi)|$ and $|\pi|$ can be constructed by starting with the finest optimal partition $\left\{\left\{x, x^{-1}\right\}: x \in G\right\}$ and using the following fact:

Let $\pi$ be an optimal partition of $G$ and let $A \subseteq G$. Let $\pi_{1}$ be the finest partition of $G$ such that $\pi \leq \pi_{1}$ and $\bar{A} \subseteq \operatorname{St}\left(\pi_{1}\right)$, and let $\pi_{2}$ be the finest partition of $G$ such that $\pi \leq \pi_{2}$ and $A \subseteq Z\left(\pi_{2}\right)$. Then the partitions $\pi_{1}$ and $\pi_{2}$ are also optimal.

In this section we construct the partially ordered set of optimal partitions of the dihedral group $D_{p}$, where $p>2$ is prime, and compute explicitly the number $\left|S_{r}\left(D_{p}\right)\right|$ of symmetric $r$-colorings of $D_{p}$ and the number $\left|S_{r}\left(D_{p}\right) / \sim\right|$ of equivalence classes of symmetric $r$-colorings.

The dihedral group $D_{p}$ has the following lattice of subgroups:

Now we list all optimal partitions $\pi$ of $D_{p}, p>2$ together with parameters $|\operatorname{St}(\pi)|,|Z(\pi)|$ and $|\pi|$.

The finest partition

$$
\begin{aligned}
& \pi:\{e\},\{s\},\{s a\}, \ldots,\left\{s a^{p-1}\right\},\left\{a, a^{p-1}\right\}, \ldots \\
& \operatorname{St}(\pi)=\{e\}, Z(\pi)=\{e\} \\
& |S t(\pi)|=1,|Z(\pi)|=1,|\pi|=p+1+\frac{p-1}{2}=\frac{3 p+1}{2}
\end{aligned}
$$

$p$ partitions of the form
$\pi:\{e\},\left\{a, a^{p-1}\right\}, \ldots,\{s\},\left\{s a, s a^{p-1}\right\}, \ldots$
$S t(\pi)=\{e\}, Z(\pi)=\{e, s\}$,
$|S t(\pi)|=1,|Z(\pi)|=2,|\pi|=\frac{p-1}{2} \cdot 2+2=p+1$.
One partition

$$
\begin{aligned}
& \pi:\left\{e, a, \ldots, a^{p-1}\right\},\{s\},\{s a\}, \ldots,\left\{s a^{p-1}\right\} \\
& \operatorname{St}(\pi)=\{e\}, Z(\pi)=\left\{e, a, \ldots, a^{p-1}\right\}, \\
& |\operatorname{St}(\pi)|=1,|Z(\pi)|=p,|\pi|=p+1 .
\end{aligned}
$$

One partition

$$
\begin{aligned}
& \pi:\{e\},\left\{a, a^{p-1}\right\}, \ldots,\left\{s, s a, \ldots, s a^{p-1}\right\} \\
& \operatorname{St}(\pi)=\{e\}, Z(\pi)=\left\{e, s, s a, \ldots, s a^{p-1}\right\}, \\
& |\operatorname{St}(\pi)|=1,|Z(\pi)|=p+1,|\pi|=\frac{p-1}{2}+2=\frac{p+3}{2} .
\end{aligned}
$$

$p$ partitions of the form
$\pi:\left\{e, a, \ldots, a^{p-1}\right\},\{s\},\left\{s a, s a^{p-1}\right\}, \ldots$
$S t(\pi)=\{e\}, Z(\pi)=\left\{e, a, \ldots, a^{p-1}, s\right\}$,
$|S t(\pi)|=1,|Z(\pi)|=p+1,|\pi|=\frac{p-1}{2}+2=\frac{p+3}{2}$.
$p$ partitions of the form

$$
\begin{aligned}
& \pi:\{e, s\},\left\{a, a^{p-1}, s a, s a^{p-1}\right\}, \ldots \\
& \operatorname{St}(\pi)=\{e, s\}, Z(\pi)=\{e, s\}, \\
& |\operatorname{St}(\pi)|=2,|Z(\pi)|=2,|\pi|=\frac{p-1}{2}+1=\frac{p+1}{2} .
\end{aligned}
$$

One partition

$$
\begin{aligned}
& \pi:\left\{e, a, \ldots, a^{p-1}\right\},\left\{s, s a, \ldots, s a^{p-1}\right\} \\
& \operatorname{St}(\pi)=\left\{e, a, \ldots, a^{p-1}\right\}, Z(\pi)=D_{p}, \\
& |S t(\pi)|=p,|Z(\pi)|=2 p,|\pi|=2 .
\end{aligned}
$$

And the coarsest partition

$$
\begin{aligned}
& \pi:\left\{D_{p}\right\} \\
& \operatorname{St}(\pi)=D_{p}, Z(\pi)=D_{p} \\
& |\operatorname{St}(\pi)|=2 p,|Z(\pi)|=2 p,|\pi|=1
\end{aligned}
$$

Next, we draw the partially ordered set of optimal partitions $\pi$ together with parameters $|S t(\pi)|,|Z(\pi)|$ and $|\pi|$. The picture below shows also the values of the Möbius function of the form $\mu(a, 1)$.

Finally, by Theorem 3, we obtain that

$$
\begin{aligned}
\left|S_{r}\left(D_{p}\right)\right| & =\left|D_{p}\right| \sum_{x \in P} \sum_{y \leq x} \frac{\mu(y, x)}{|Z(y)|} r^{|x|} \\
& =2 p\left(r^{\frac{3 p+1}{2}}+p r^{p+1}\left(\frac{1}{2}-1\right)+r^{p+1}\left(\frac{1}{p}-1\right)+\right. \\
& +p r^{\frac{p+3}{2}}\left(\frac{1}{p+1}-\frac{1}{2}-\frac{1}{p}+1\right)+ \\
& +r^{\frac{p+3}{2}}\left(\frac{1}{p+1}-\frac{p}{2}+p-1\right)+p r^{\frac{p+1}{2}}\left(\frac{1}{2}-\frac{1}{2}\right)+ \\
& +r^{2}\left(\frac{1}{2 p}-\frac{1}{p+1}-\frac{p}{p+1}+\frac{p}{2}+\frac{p-1}{p}-p+1\right)+ \\
& \left.+r\left(\frac{1}{2 p}-\frac{1}{2 p}-\frac{p}{2}+\frac{p}{2}\right)\right)= \\
& =2 p\left(r^{\frac{3 p+1}{2}}-\frac{p}{2} r^{p+1}-\frac{p-1}{p} r^{p+1}+(p-1) r^{\frac{p+3}{2}}+\right. \\
& \left.+\frac{-p^{2}+2 p-1}{2 p} r^{2}\right)= \\
& =2 p\left(r^{\frac{3 p+1}{2}}+\frac{-p^{2}-2 p+2}{2 p} r^{p+1}+(p-1) r^{\frac{p+3}{2}}-\right. \\
& \left.-\frac{(p-1)^{2}}{2 p} r^{2}\right)= \\
& =2 p r^{\frac{3 p+1}{2}}+\left(-p^{2}-2 p+2\right) r^{p+1}+2 p(p-1) r^{\frac{p+3}{2}}- \\
& -(p-1)^{2} r^{2},
\end{aligned}
$$

$$
\begin{aligned}
\left|S_{r}\left(D_{p}\right) / \sim\right| & =\sum_{x \in P} \sum_{y \leq x} \frac{\mu(y, x)|S t(y)|}{|Z(y)|} r^{|x|} \\
& =r^{\frac{3 p+1}{2}}+p r^{p+1}\left(\frac{1}{2}-1\right)+r^{p+1}\left(\frac{1}{p}-1\right)+ \\
& +p r^{\frac{p+3}{2}}\left(\frac{1}{p+1}-\frac{1}{2}-\frac{1}{p}+1\right)+ \\
& +r^{\frac{p+3}{2}}\left(\frac{1}{p+1}-\frac{p}{2}+p-1\right)+p r^{\frac{p+1}{2}}\left(\frac{2}{2}-\frac{1}{2}\right)+ \\
& +r^{2}\left(\frac{p}{2 p}-\frac{1}{p+1}-\frac{p}{p+1}+\frac{p}{2}+\frac{p-1}{p}-p+1\right)+ \\
& +r\left(\frac{2 p}{2 p}-\frac{p}{2 p}-\frac{2 p}{2}+\frac{p}{2}\right)= \\
& =r^{\frac{3 p+1}{2}}-\frac{p}{2} r^{p+1}-\frac{p-1}{p} r^{p+1}+(p-1) r^{\frac{p+3}{2}}+ \\
& +\frac{p}{2} r^{\frac{p+1}{2}}+\frac{-p^{2}+3 p-2}{2 p} r^{2}+\frac{1-p}{2} r= \\
& =r^{\frac{3 p+1}{2}}+\frac{-p^{2}-2 p+2}{2 p} r^{p+1}+(p-1) r^{\frac{p+3}{2}}+ \\
& +\frac{p}{2} r^{\frac{p+1}{2}}+\frac{-p^{2}+3 p-2}{2 p} r^{2}+\frac{1-p}{2} r .
\end{aligned}
$$

Thus, we have showed that
Theorem 4. For every $r \in \mathbb{N}$ and prime $p>2$,

$$
\begin{aligned}
& \left|S_{r}\left(D_{p}\right)\right|=2 p r^{\frac{3 p+1}{2}}+\left(-p^{2}-2 p+2\right) r^{p+1}+ \\
& +2 p(p-1) r^{\frac{p+3}{2}}-(p-1)^{2} r^{2} \\
& \left|S_{r}\left(D_{p}\right) / \sim\right|=r^{\frac{3 p+1}{2}}+\frac{-p^{2}-2 p+2}{2 p} r^{p+1}+(p-1) r^{\frac{p+3}{2}}+ \\
& +\frac{p}{2} r^{\frac{p+1}{2}}+\frac{-p^{2}+3 p-2}{2 p} r^{2}+\frac{1-p}{2} r .
\end{aligned}
$$

Notice that the number of all $r$-colorings of $D_{p}$ is $r^{2 p}$ and the number of equivalence classes of all $r$-colorings of $D_{p}$ is

$$
\frac{1}{\left|D_{p}\right|} \sum_{g \in D_{p}} r^{\left|D_{p} /\langle g\rangle\right|}=\frac{1}{2 p}\left(r^{2 p}+p r^{p}+(p-1) r^{2}\right)
$$

## 3 Conclusion

We conclude with the following open question
Question 1. What is the number of equivalence classes of symmetric $r$-colorings of the dihedral group $D_{n}$, where $r, n \in \mathbb{N}$ ?
