Published online: 1 Jun. 2013

Abstract: Mixed logit is a highly flexible model that can approximate any random utility model. In this paper, two kinds of mixed multinomial logit models were considered. The main aim was to introduce a locally D-optimal criterion to obtain an optimal combination of the levels of attributes for producing alternatives and an optimal combination of alternatives in choice sets. Thus, a design including choice sets as the support points was designed.

Keywords: Mixed Logit models; Conjoint choice experiments; Multinomial Logit models; D-optimal criterion

1 Introduction

Like probit logit models, the mixed logit model has been known for many years; but, it has just become fully applicable since the advent of simulation. The first application of mixed logit was apparently in automobile demand models created jointly by [4] and [6]. In these studies, the explanatory variables did not vary over decision makers, and the observed dependent variable was market shares rather than individual customer’s choices. As a result, the computationally intensive integration that is inherent in the mixed logit was needed to be performed only once for the market as a whole rather than for each decision maker in a sample. Early applications on customer-level data, such as [15] and [1], included only one or two dimensions of integration, which could be calculated by quadrature. Improvements in computer speed and in the understanding of simulation methods have allowed the full power of mixed logit to be utilized.

Among the studies to evidence this power are those conducted by [2] and [5] on cross-sectional data, and [7], [12] and [3] on panel data.

Mixed logit models can be derived under a variety of different behavioral specifications and each derivation provides a particular interpretation. The mixed logit model is defined on the basis of the functional form for its choice probabilities. Any behavioral specification, derived choice probability take this particular form, is called a mixed logit model. Mixed logit probabilities are the integrals of standard logit probabilities over a density of parameters. In this paper, the information matrix was required to be known which was calculated by the choice probabilities related to both random and fix attributes. Then, a design based on choice sets was introduced in order to obtain the best choice of the alternatives produced by combining the levels of the attributes.

Therefore, this paper is composed of three sections. First of all, model specifications are described. The optimal criterion is introduced in the second section. At last, conclusion is presented.

2 Model Specifications

Considering the random utility of the standard MNL model [9], if heterogeneity is taken into account in the parameter across consumers, then the following utility function can be defined:

\[
U_{ij s} = \mathbf{f}^T_i (a_{js}) \mathbf{B}_{j s} + \mathbf{e}_{ij s}; \quad \{ i = 1, 2, \ldots, N, \text{ the number of Individuals};
\]
\[
\{ j = 1, 2, \ldots, J, \text{ the number of Alternatives};
\]
\[
\{ s = 1, 2, \ldots, S, \text{ the number of Choice sets}. \}
\]

where,

\[
f_i (a_{js}) = (f_{i1} (a_{js}), f_{i2} (a_{js}), \ldots, f_{iK} (a_{js}))^T,
\]
\[
f_k (a_{js}) = (f_{k1} (a_{js}), f_{k2} (a_{js}), \ldots, f_{kL} (a_{js}))^T
\]

characterize the levels of attribute \(k\) and \(C_\alpha = \{f_{k} (a_{\mu})\}_{j=1, \ldots, J}^{K=1, \ldots, K}\) denotes the choice set with \(J\)

* Corresponding author e-mail: jafari_habib@yahoo.com
alternatives. Thus, it is assumed that the parameter vector \( \beta = (\beta_1, \beta_2, \ldots, \beta_L)^T \) is different from all individuals and has multivariate normal distribution with mean \( \mu_i = (\mu_{i1}, \mu_{i2}, \ldots, \mu_{iL})^T \) and variance \( \Sigma_i \), where there are \( K \) attributes, each with \( L_k \) levels. Since \( \beta_i \) is said to be different from all individuals, then \( \beta_i \) is a random variable. Each individual selects a part of levels of attributes, not all of their levels. Thus, the following can be considered:

\[
\beta_{ik} = (\beta_{i1k}, \beta_{i2k}, \ldots, \beta_{iL_kk})^T,
\]

where \( L_k \leq L_k; k = 1, \ldots, K \). Considering the effects-type coding, the following can be given:

\[
\sum_{k=1}^{L_k} \beta_{ik} = 0, \quad \sum_{k=1}^{L_k} \beta_{ik} \neq 0.
\]

Now, it is supposed that \( \beta_{i\ell} \) and \( \beta_{i\ell'} \); \( \forall \ell \neq \ell' \) (\( \ell = 1, 2, \ldots, L_k \)) are not correlate; thus:

\[
\text{cov}(\beta_{i\ell}, \beta_{i\ell'}) = \begin{cases} 
\sigma_{\beta_{i\ell}}, & \ell = \ell' \\
0, & \ell \neq \ell'.
\end{cases}
\]

Also:

\[
\text{Cov}(\beta_{i\ell}, \beta_{i\ell'}) = \left( \Sigma_i, k = k' \right); \\
0, & k \neq k'.
\]

where \( \Sigma_k = \text{diag} (\sigma_{\beta_{i1k}}, \sigma_{\beta_{i2k}}, \ldots, \sigma_{\beta_{iL_kk}}) \). Thus,

\[
\Sigma = \bigotimes_{k=1}^{K} \Sigma_k.
\]

In this kind of situation, the following case should be concentrated on:

\[
\beta_{ik} \sim N_{L_k}(\mu_{ik}; \Sigma_k) \quad \text{and} \quad \beta_i \sim N_{p}(\mu_i; \Sigma_i). (2)
\]

where \( p = \sum_{k=1}^{K} L_k \). Now, with respect to (2):

\[
\beta_i = \mu_i + \mathbf{V} \sigma_i, \quad \text{(3)}
\]

where \( \mathbf{V} = \bigotimes_{k=1}^{K} \mathbf{V}_k; \quad \mathbf{V}_k = \text{diag}(\mathbf{v}_{k1}, \mathbf{v}_{k2}, \ldots, \mathbf{v}_{kL_k}) \) is a diagonal matrix with pair wise with independent standard normal elements on the diagonal and \( \sigma_i = (\sigma_{i1}, \sigma_{i2}, \ldots, \sigma_{iL_k})^T; \quad \sigma_i = (\sigma_{1k}, \sigma_{2k}, \ldots, \sigma_{L_kk})^T \).

According to the above description, the obtained model is called the mixed or heterogeneous logit model [5]. Since \( \beta_i \) is random variable, then it can be written as follows:

\[
p_i(a_j; \beta_i) = \frac{\exp(f_i^T(a_j)\beta_i)}{\sum_{j=1}^{J} \exp(f_i^T(a_j)\beta_i)}, \quad \text{(4)}
\]

where \( p_i(a_j; \beta_i) = P(Y_{ij} = 1|\beta_i) \) is the conditional probability in which individual \( i \) selects alternative \( a_j \) in the choice set \( s \) and (with respect to (1));

\[
Y_{ij} = \begin{cases} 
1, & \text{if } U_{ij} = \text{max}_{j' \in c_i} U_{ij'}; \\
0, & \text{otherwise}.
\end{cases}
\]

But in the MMNL models,

\[
\mathcal{P}_i(a_j; \theta_i) = P(Y_{ij} = 1|\theta_i); \quad \theta_i = (\mu_i^T, \sigma_i^T)^T
\]

the unconditional probability that alternative \( a_j \) is selected by individual \( i \) (4) so that:

\[
\mathcal{P}_i(a_j; \theta_i) = \int_{\mathbb{R}^p} p_i(a_j; \beta_i) g(\beta_i|\theta_i) d\beta_i
\]

\[
= \int_{\mathbb{R}^p} p_i(a_j; (\mu_i + \mathbf{V} \sigma_i)) \phi(\mathbf{V}_1) \cdots \phi(\mathbf{V}_K) d\mathbf{V}
\]

\[
= \int_{\mathbb{R}^p} \exp(f_i^T(a_j)(\mu_i + \mathbf{V} \sigma_i)) \phi(\mathbf{V}_1) \cdots \phi(\mathbf{V}_K) d\mathbf{V}
\]

where \( \phi(.) \) is the normal standard density function. There is not an analytical method for calculating integral (5). In these kinds of situations, Quadrature (Gauss-Hmrite quadrature) technique can be used; but, it must be noted that if the dimension of integration is greater than two, Quadrature technique cannot compute the integrals in sufficient speed and precision for maximum likelihood estimation. Thus, simulation techniques are usually applied for estimating Mixed Logit models. According to the previous description, the integrals in the choice probabilities are approximated using a Mote-Carlo technique; then, the resulting simulated log-likelihood function is maximized. For a given \( \theta_i \), a vector of values for \( \beta_i \) is drawn from \( g(\beta_i|\theta_i) \) for individual. the values of this draw can then be used to calculate \( p_i(a_j|\beta_i) \). This process is repeated \( R \) times, meaning that:

\[
\beta_i^{(1)}; \ldots; \beta_i^{(R)} \sim i.i.d \quad N_p(\mu_i; \Sigma_i);
\]

\[
\beta^{(r)}_i = \mu_i + \mathbf{V}^{(r)}_i \sigma_i; \quad \forall i = 1, 2, \ldots, N, \quad r = 1, 2, \ldots, R,
\]

where integration over \( g(\beta_i|\theta_i) \) is approximated by averaging the \( R \) draws. If it is supposed that

\[
\hat{p}_i(a_j|\beta_i^{(r)}) = \frac{\exp(f_i^T(a_j)\beta_i^{(r)})}{\sum_{j=1}^{J} \exp(f_i^T(a_j)\beta_i^{(r)})}
\]

is the realization of the choice probability related to the choosing alternative \( a_j \) by individual \( i \) for the \( r \)th draw of \( \beta_i \), then this can be written;

\[
\mathcal{P}_i(a_j; \theta_i) = \frac{1}{R} \sum_{r=1}^{R} \hat{p}_i(a_j|\beta_i^{(r)}), \quad \text{(9)}
\]

where \( \mathcal{P}_i(a_j; \theta_i) \) is the simulated choice probability of individual \( i \) choosing alternative \( a_j \) given \( \theta_i \). In this situation, the Simulated Log-Likelihood function can be defined as follows;

\[
\mathcal{F}_i(\theta_i) = \sum_{i=1}^{N} \sum_{j=1}^{J} Y_{ij} \ln \left( \mathcal{P}_i(a_j; \theta_i) \right). \quad \text{(10)}
\]
The estimated parameter vector $\hat{\theta}$ is the vector that maximizes the Simulated Log-Likelihood.

Additionally, it is supposed that there are two kinds of attributes. One part has fixed parameters which include $K_1$ attributes, each with $L_k: k = 1, \ldots, K_1$ levels. Another group has random parameters which consist $K_2$ attributes, each with $L_k: k = K_1 + 1, \ldots, K$ levels. Therefore, the utility function is introduced as follows:

$$U_{ijs} = f_i^T(a_{ij})\beta + h_i^T(b_{ijs}) + \epsilon_{ijs},$$  \hspace{1cm} (11)

where $\beta = (\beta_1, \beta_2, \ldots, \beta_K)^T$ (according to effects-type coding) for fixed parameters; and $b_i = (b_{i1}, b_{i2}, \ldots, b_{iK})^T$ (according to effects-type coding) for random parameters and $\sum_{k=1}^{K} b_{ik} \neq 0$ is not the same for all the individuals and is a random variable, for example, with the multivariate normal distribution:

$$b_i \sim N_p(\mu_{b_i}, \sigma_{b_i}) : \forall i = 1, 2, \ldots, N$$

where $p_1 = \sum_{k=1}^{K_1} L_k - 1$ and $p_2 = \sum_{k=K_1+1}^{K} L_k$ are the dimension of the fixed and random parameters, respectively. Similar to (8) and (9), this can be written:

$$P_{i}(a_{ij}|b_i) = \frac{\exp(f_i^T(a_{ij})\beta + h_i^T(b_{ijs})b_i)}{\sum_{j'=1}^{J} \exp(f_i^T(a_{ij'})\beta + h_i^T(b_{ijs})b_i)}.$$  \hspace{1cm} (12)

If $\eta_i$ is assumed to be the parameter vector of the distribution function of $b_i$, meaning that $g(b_i|\eta_i)$; thus, two type parameters, $\beta$ and $\eta_i$, will be present so that:

$$P_{i}(a_{ij}|V_i) = \frac{\exp(f_i^T(a_{ij})\beta + h_i^T(b_{ijs})b_i + \mathbf{\mu}_b^T \mathbf{\eta}_i)}{\sum_{j'=1}^{J} \exp(f_i^T(a_{ij'})\beta + h_i^T(b_{ijs})b_i + \mathbf{\mu}_b^T \mathbf{\eta}_i)},$$

where $P_{i}(a_{ij}|V_i)$ is the probability of individual $i$ choosing alternative $a_j$ for the $r$th draw "$b_i$"; then the following can be given:

$$P_{i}(a_{ij}|V_i) = \frac{1}{R} \sum_{r=1}^{R} P_{i}(a_{ij}|b_i^{(r)})$$  \hspace{1cm} (13)

where $P_{i}(a_{ij}|b_i^{(r)})$ is the simulated choice probability of individual $i$ choosing alternative $a_j$ given $\eta_i$. Thus, the Simulated Log-Likelihood function is defined as follows:

$$\mathcal{L}_i(\beta, \eta_i) = \prod_{i=1}^{N} \prod_{j=1}^{J} Y_{ijs} \ln \left(P_{i}(a_{ij}|\beta, \eta_i)\right).$$  \hspace{1cm} (14)

The estimated parameter vectors $\hat{\beta}$ and $\hat{\eta}$ are the vectors that maximize the Simulated Log-Likelihood function.

### 3 Optimal Criterion

In this section, the D-optimal criterion is introduced for the Mixed MNL (MMNL) model. For this purpose, the information matrix of the MMNL model should be evaluated. Since it is assumed that the choices in different choice sets are independent, the information matrix based on (12) for each choice set, $s$, is as follow:

$$I(\beta, \eta_i|C_s) = -E \left( \frac{\partial^2 \mathcal{L}_i(\beta, \eta_i)}{\partial \beta \partial \eta_i} \right).$$

where $E(.)$ denotes the expectation of the random variable.

Now, for simplicity, the above matrix is rewritten as follow:

$$I(\beta, \eta_i|C_s) = \begin{vmatrix} \mathcal{D}_{ss} & \mathcal{D}_{s1} \end{vmatrix}$$

along with

$$\mathcal{D}_{ss} = \sum_{r=1}^{R} \sum_{j=1}^{J} \sum_{s} \left[ P_{ijr}(V) - P_{ijr}(V) P_{ijr}(V) F_{ijr} \right] dV$$

$$\mathcal{D}_{s1} = \sum_{r=1}^{R} \sum_{j=1}^{J} \sum_{s} \left[ P_{ijr}(V) - P_{ijr}(V) P_{ijr}(V) H_{ijr} \right] dV$$

where, $\eta_i = (\mathbf{\mu}_b^T, \sigma_b^T)^T$, $P_{ijr}(V) = (p_{ijr(a_{ijr}^1)}, p_{ijr(a_{ijr}^2)}, \ldots, p_{ijr(a_{ijr}^s)})^T$, $\eta_{ijr} = (\mathbf{\mu}_b^T, \sigma_b^T)$, $F_{ijr} = [f_{ijr(a_{ijr})}]_{j=1,2,...,J}$ and $H_{ijr} = [h_{ijr(a_{ijr})}]_{j=1,2,...,J, k=1,2,...,K}$ are design matrices. See appendix A.

To calculate integrals (14), there are no analytical techniques; thus, they should be calculated by the Monte-Carlo technique. Now, the distribution of the matrix $V$ and the random sample with size $n$ from its distribution mean that:

$$V^{(1)}, V^{(2)}, \ldots, V^{(n)} \sim i.i.d N(p_2, 0, I_{p_2}),$$

where, $I_{p_2}$ is a $p_2$-dimensional identical matrix; thus, (14) can be rewritten as:

$$\mathcal{D}_{ss}^{(n)} = \frac{1}{n} \sum_{m=1}^{n} [P_{ijr}(V^{(m)}) - p_{ijr}(V^{(m)} p_{ijr}(V^{(m)}))] F_{ijr}$$

$$\mathcal{D}_{s1}^{(n)} = \frac{1}{n} \sum_{m=1}^{n} [P_{ijr}(V^{(m)}) - p_{ijr}(V^{(m)} p_{ijr}(V^{(m)}))] H_{ijr}$$

$$\mathcal{P}_{ijr}^{(n)}(a_{ijr}|\eta_i) = \frac{1}{n} \sum_{m=1}^{n} p_{ijr}(a_{ijr}|\eta_i)$$

$$P_{ijr}^{(m)}(a_{ijr}|\eta_i) = \frac{\exp(f_i^T(a_{ijr})\beta + h_i^T(b_{ijs})\eta_i)}{\sum_{j'=1}^{J} \exp(f_i^T(a_{ijr'})\beta + h_i^T(b_{ijs})\eta_i)}$$

$$\partial^2 \mathcal{L}_i(\beta, \eta_i)$$
Now, based on Equations (15), the following can be presented:

\[ I^0(\beta, \eta_i|C_i) = \left( \begin{array}{c} \frac{\partial I^n(\beta, \eta_i|C_i)}{\partial \beta_i} \\ \frac{\partial I^n(\beta, \eta_i|C_i)}{\partial \eta_i} \end{array} \right) \]  

(16)

In this situation and based on the number of the levels of the fixed and random attributes: \( \mathcal{L}_1, \mathcal{L}_2, \ldots, \mathcal{L}_{K_k}, L_{K_k+1}, \ldots, L_K \). The total number of alternatives can be obtained as follows:

\[ J = \prod_{k=1}^{K_k} \mathcal{L}_k \prod_{k=K_k+1}^K L_k. \]

In this paper, since the designs with the same number of choice sets are considered for each individual; thus these designs have \( S \) choice sets as support points. Consequently, since \( \mathcal{J} = \left( \begin{array}{c} J \\ S \end{array} \right) \) denotes the total number of choice sets, each with \( J \) alternatives, then just a part of them is considered where \( \mathcal{J} / S \) denotes the total number of choice sets, each with \( J \) alternatives.

Similar to classical MNL models [9], a criterion can be defined in order to obtain a locally D-optimality criterion as follow (for individual \( i \)):

\[ \Psi(\text{Mixed})(\xi|\beta, \eta) = -\ln \left( \det \left( I^n(\beta, \eta|\xi) \right) \right) \]

(17)

where, \( I^n(\beta, \eta|\xi) = \sum_{s=1}^S w_{is} \cdot I^n(\beta, \eta_i|C_i) \) for design \( \xi \), which includes \( S \) support points as follows:

\[ \xi = \left\{ \begin{array}{l} C_{1i} \quad C_{2i} \quad \ldots \quad C_{Si} \\ w_{1i} \quad w_{2i} \quad \ldots \quad w_{Si} \end{array} \right\} \in \Xi_i; \quad \forall i = 1, 2, \ldots, N. \]

(18)

Now, based on (18) and to obtain the locally D-optimal design, a new design can be defined in the following way (because they are identifiable for the parameters of the model):

\[ \xi = \sum_{i=1}^N \alpha_i \cdot \xi_i, \]

(19)

where (Convex combination property):

\[ \Psi(\text{Mixed})(\xi|\beta, \eta) \leq \sum_{i=1}^N \alpha_i \cdot \Psi(\text{Mixed})(\xi_i|\beta, \eta), \]

(20)

such that:

\[ \xi = \left\{ \begin{array}{l} C_1 \quad C_2 \quad \ldots \quad C_S \\ w_1 \quad w_2 \quad \ldots \quad w_S \end{array} \right\} \in \Xi, \]

(21)

where

\[ C_1 = C_{1i}, \quad C_S = C_{Si}, \]

\[ w_1 = \alpha_{1i} w_{1i}, \quad w_2 = \alpha_{1i} w_{2i}, \quad \ldots \]

\[ = \alpha_{Si} w_{Si}. \]

Also, it can be written as:

\[ \Psi(\text{Mixed})(\xi|\beta, \eta) = -\ln \left( \det \left( I^n(\beta, \eta|\xi) \right) \right). \]

(22)

where

\[ I^n(\beta, \eta|\xi) = \sum_{s=1}^S w_{is} \cdot I^n(\beta, \eta_i|C_i); \]

\[ \eta = (\eta_1, \eta_2, \ldots, \eta_N)^T \]

and

\[ \eta_i = (\mu_{1i}, \mu_{2i}, \ldots, \mu_{K Kl}\sigma_{1i}, \ldots, \sigma_{K Kl})^T; i = 1, 2, \ldots, N. \]

With respect to (11), the number of parameters is \( p = p_1 + 2p_2 \), where \( p_1 \) denotes the number of parameters for fix attributes and \( 2p_2 \) is the number of parameters for random attributes. Thus, to obtain the optimal combination of the levels of attributes for producing alternatives and the optimal combination of alternatives in choice sets design (21) can be considered, where \( \Xi \) can be hold in interval \( [\beta_0, \beta_0 + 1] \) (Caratheodory’ theorem [8]). In this case, \( \xi^* \) is the locally D-optimal design if:

\[ \xi^* = \arg \min_{\xi \in \Xi} \Psi(\text{Mixed})(\xi|\beta_0, \eta_0), \]

(22)

where \( \beta_0, \eta_0 \) denote the true values of parameters and \( \Xi = \bigcup_{i=1}^N \Xi_i; \forall i = 1, 2, \ldots, N \), where:

\[ \Xi_i = \left\{ \left( C_{is}, w_{is} \right) | 0 \leq w_{is} \leq 1; \sum_{s=1}^S w_{is} = 1; \quad C_{is} = \left[ F_{is} \quad H_{is} \right] \right\}. \]

4 Conclusion

In marketing and business, there are many important things like the quality on which the combination of attributes (products or services) depends. But, there exist an important thing, without which all these products or services are meaningless; that is the customer. If customers needs are satisfied, then, success will be achieved; otherwise: not.

It is known that a customer tends to choose an alternative (product or service) which has the highest utility; thus, a model is required which can show this situation. One of the most important introduced model is the MNL model which belongs to the logit family. Of course, this model (MNL) can be used when all alternatives are independent; in other words, when IIA is hold; otherwise, other models of the logit family should be used which include two-level or three-level NMNL models [10].

In this kind of models, the focus should be on the combination of the levels of attributes (alternatives) and the combination of alternatives in choice sets.

To obtain the best combination, the levels of attributes and the most suitable combination of choice sets, the optimal design can be a nice idea.
There are many criteria to obtain optimal design for do this idea; but, in this paper, only the D-optimal criterion was introduced because this criterion was not affected by reparameterizations of the model [13].

The D-optimal criterion for the MMNL model is a function of the determinate of information matrix, depending on unknown parameters as the standard MNL was introduced because this criterion was not affected by this idea; but, in this paper, only the D-optimal criterion was discussed. Also, different designs were introduced and the one which is locally more suitable was given.

**Appendix A:**

According to (14):

\[
\frac{\partial S(\beta, \eta_i)}{\partial \beta} = 
\]

\[= \sum_{j=1}^{J} Y_{ij} \frac{\partial \ln(\mathcal{P}_i(a_j|\eta_i))}{\partial \beta} \]

\[= \sum_{j=1}^{J} Y_{ij} \mathcal{P}_i^{-1}(a_j|\eta_i) \left( \mathcal{L}_i(a_j) \mathcal{P}_i(a_j|\eta_i) - \int_{\mathcal{D}} p_i(a_j|\eta_i) \mathbf{p}_i^T(V)F_i d\Phi(V) \right) \]

\[= \sum_{j=1}^{J} Y_{ij} \mathcal{L}_i - \int_{\mathcal{D}} \sum_{j=1}^{J} Y_{ij} p_i(a_j|\eta_i) \mathcal{P}_i^{-1}(a_j|\eta_i) \mathbf{p}_i^T(V)F_i d\Phi(V) \]

\[= \mathbf{Y}_i^T F_i - \int_{\mathcal{D}} \mathbf{Y}_i^T \mathcal{P}_i^{-1} \mathbf{p}_i(V) \mathbf{p}_i^T(V)F_i d\Phi(V) \]

\[= \mathbf{Y}_i^T \mathcal{P}_i^{-1} \left( \mathbf{F}_i - \int_{\mathcal{D}} \mathbf{p}_i(V) \mathbf{p}_i^T(V)F_i d\Phi(V) \right) \]

\[= \mathbf{Y}_i^T \mathcal{P}_i^{-1} \left( \int_{\mathcal{D}} \mathbf{p}_i(V)F_i d\Phi(V) - \int_{\mathcal{D}} \mathbf{p}_i(V) \mathbf{p}_i^T(V)F_i d\Phi(V) \right) \]

\[= \mathbf{Y}_i^T \mathcal{P}_i^{-1} \left( \int_{\mathcal{D}} \left( \mathbf{p}_i(V) - \mathbf{p}_i(V) \mathbf{p}_i^T(V) \right) F_i d\Phi(V) \right) \]

Similarly;

\[
\frac{\partial S(\beta, \eta_i)}{\partial \beta^T} = \left( \int_{\mathcal{D}} \left( \mathbf{p}_i(V) - \mathbf{p}_i(V) \mathbf{p}_i^T(V) \right) F_i d\Phi(V) \right)^T \mathcal{P}_i^{-1} \mathbf{Y}_i, \]

thus;

\[
E \left( \frac{\partial S(\beta, \eta_i)}{\partial \beta^T} \right) \frac{\partial S(\beta, \eta_i)}{\partial \beta} = \mathcal{P}_i^{-1} E \left( \mathbf{Y}_i \mathbf{Y}_i^T \right) \mathcal{P}_i^{-1} \mathcal{D}_i = \mathcal{D}_i \mathcal{P}_i^{-1} \mathcal{D}_i \]
where $\int_{\mathcal{R}^2} P_i(V) \, d\Phi(V) = P_i$ and:

$$Y_iY_i^T = \begin{pmatrix} Y_{1i}^2 & Y_{1i}Y_{2i} & \cdots & Y_{1i}Y_J \\ Y_{2i}Y_{1i} & Y_{2i}^2 & \cdots & Y_{2i}Y_J \\ \vdots & \vdots & \ddots & \vdots \\ Y_JY_{1i} & Y_JY_{2i} & \cdots & Y_J^2 \end{pmatrix} \Rightarrow E(Y_iY_i^T) = \begin{pmatrix} P_i(a_1|\beta_i) & 0 & \cdots & 0 \\ 0 & P_i(a_2|\beta_i) & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & P_i(a_J|\beta_i) \end{pmatrix} = P_i$$

Similarity, the following can be given:

$$\frac{\partial S(\beta, \eta_i)}{\partial \mu_i} = Y_i^T P_i^{-1} \left( \int_{\mathcal{R}^2} (P_i(V) - p_i(V)p_i^T(V)) \, H_i \, d\Phi(V) \right) = Y_i^T P_i^{-1} \mathcal{M}_i$$

$$\frac{\partial S(\beta, \eta_i)}{\partial \sigma_i} = Y_i^T P_i^{-1} \left( \int_{\mathcal{R}^2} (P_i(V) - p_i(V)p_i^T(V)) \, H_i V \, d\Phi(V) \right) = Y_i^T P_i^{-1} \mathcal{Q}_i$$

Hence:

$$E \left( \frac{\partial S(\beta, \eta_i)}{\partial \mu_i} \frac{\partial S(\beta, \eta_i)}{\partial \mu_i} \right) = \mathcal{M}_i^T P_i^{-1} E \left( Y_iY_i^T \right) P_i^{-1} \mathcal{M}_i = \mathcal{M}_i^T P_i^{-1} \mathcal{M}_i$$

$$E \left( \frac{\partial S(\beta, \eta_i)}{\partial \sigma_i} \frac{\partial S(\beta, \eta_i)}{\partial \sigma_i} \right) = \mathcal{Q}_i^T P_i^{-1} E \left( Y_iY_i^T \right) P_i^{-1} \mathcal{Q}_i = \mathcal{Q}_i^T P_i^{-1} \mathcal{Q}_i$$

$$E \left( \frac{\partial S(\beta, \eta_i)}{\partial \mu_i} \frac{\partial S(\beta, \eta_i)}{\partial \sigma_i} \right) = \mathcal{M}_i^T P_i^{-1} E \left( Y_iY_i^T \right) P_i^{-1} \mathcal{Q}_i = \mathcal{M}_i^T P_i^{-1} \mathcal{Q}_i$$

---

**Habib Jafari**

received the MS degree in Mathematical Statistics from Shiraz University in 2000 (Iran), and the PhD degree in Mathematical Statistics (Conjoint Analysis) from the IMST, OvG University of Magdeburg in 2010 (Germany). He is currently an assistant professor in Razi University. His research interests are in the areas of optimal design, conjoint Analysis
