Published online: 1 January 2012

Abstract: In this paper, an improved GEP (Gene Expression Programming based on Block Strategy, BS-GEP) is proposed in consideration of the characteristics of software reliability growth models, on which a new software reliability modeling method is formed. Block strategy is the key point of BS-GEP, in which the population is divided into several blocks according to the individual fitness of each generation and the genetic operators are reset differently in each block to guarantee the genetic diversity. The new reliability model is constructed on software failure time series using BS-GEP algorithm, and compared with the traditional models. The simulation results show that the new model has excellent goodness of fit, and its predictive ability in the short term is superior to the traditional models and classical GEP model. The new method is proved widely used for many other time sequences and has a wider versatility.

Key words: Software Reliability; Reliability Modeling; Software Failure Time series; Gene Expression Programming (GEP)

0 Introduction
An excellent reliability model can accurately assess and predict software reliability behavior. This is important for the software market decision. After the study in software reliability models gained greater development in the 1970s, many reliability models have already been put into use. So far, more than 200 models have been published\(^{1-3}\). Due to the complexity of the software logic structure, test behavior complexity, and the complexity of the failure modes, there are many debates over the basic assumptions of software reliability models, and flaws of low prediction accuracy and poor consistency in the practical application.

In this paper the new software reliability modeling is completed with the direct start from the failure time series during software testing processes, using Gene Expression Programming (GEP) for data mining. GEP, a newly proposed genetic algorithm, is an advanced technique in data mining. The data analysis and the expression discoveries capabilities is
more excellent than GAs\(^4\). Combining with the characteristics of software reliability growth models, an improved GEP (GEP based on Block Strategy, BS-GEP) is proposed, of which the algorithm complexity and convergence is analyzed later on. Then the new algorithm is adopted to construct a new software reliability model. In our work, we particularly analyzed the software testing case of Armored Force Engineering Institute\(^5,6\), to complete the new model.

Then, we calculated the model reliability parameters and compared the short-term prediction ability with GEP model and other classic probability models. All what we did is to testify the feasibility and availability of model fitting and predicting by BS-GEP algorithm.

1 GEP Fundamental

The implementation techniques of GEP include encoding, fitness function selection, genetic operators, transposition operators, recombination operators, and numerical variables. Now we just introduce the parts that will be improved in this paper.

1.1 Fitness Function Selection

Individuals that represent problem solutions need to be evaluated in all evolutionary algorithms. In GEP the solution is a computer program, or more exactly an expression. So the evaluation is to be completed by the fitting degree of data calculated by the expression and the training data. The following three ways are usually adopted\(^1\).

\[
f_i = \sum_{j=1}^{C} \left( M - \left| C_{(i,j)} - T_j \right| \right)
\]  
\[
f_i = \sum_{j=1}^{C} \left( M - \left| \frac{C_{(i,j)} - T_j}{T_j} \right| \ast 100 \right)
\]

if \( n \geq \frac{1}{2} C \), then \( f_i = n \), else \( f_i = 1 \)

where \( M \) is the range of selection, and \( C_{(i,j)} \) is the value returned by the individual program \( i \) for fitness case \( j \) (out of \( C \), fitness cases), and \( T_j \) is the target value for fitness case \( j \), and \( n \) is the number of correct cases. Note that formula (1.1) and (1.2) can be used to solve any symbolic regression problem, but formula (1.3) to logic problems. In the design of fitness function, the goal is very clear that is to make the evolutionary direction of the system in accordance with requirements.

1.2 Mutation Operator

According to Candida’s experiments\(^1\), we know that the mutation operator is the most basic and most efficient operator among all genetic operators. Mutation operator can adjust parts of gene values of the individual encoding string, to make GEP search the local space and improve the local search ability. Besides, mutation operator can change encoding structure, to maintain the population diversity, and prevent or reduce premature and jump out of local optimal solution.

Mutation operator acts on a single chromosome, and tests randomly on each code of the chromosome. When the mutation probability \( P_m \) meets a certain value (typically is 0.044), the code is re-generated. To ensure the same organizational structure, the code can be varied to any symbol of the function set and terminal set if mutation occurred in the head. Conversely, the code could be symbol of terminal set when in tail. It is can be predicted the structure of new individual generated through mutation is always correct.

2 BS-GEP Algorithm

2.1 Block Strategy

Genetic operators play an important role in the evolutionary results quality. If they are designed unreasonably, some extraordinary individuals generated in the early evolutionary could multiply rapidly and fill the population positions after several generations. So the local optimal solution, also called premature phenomenon is coming. Another way, the algorithm is close to convergence in the later stage of
evolutionary, and the fitness difference between individuals is smaller. So the potential of optimization reduced, and the result is tend to purely random selection and hardly a global optimal solution. In this paper, we adopt blocking population to make sure the population diversity of each generation. The scheme is as follows.

Step 1, suppose \( f_i, i = 1, 2, \cdots, n \) is the fitness of individual \( x_i \). Order individuals by if \( a \) block of 20, the population is divided into \( m \) blocks \( B_j, j = 1, 2, \cdots, m \) (number of \( B_m \) is permitted less than 20), \( f_{j_{-\text{max}}} \) (the fitness maximum of \( B_j \)) is less than the fitness minimum of \( B_{j+1} ( f_{(j+1){-\text{min}}}) \), that is \( f_{j_{-\text{max}}} < f_{(j+1){-\text{min}}} \).

Step 2, as in the individual fitness of each block are very close, linear or power function transformation method is adopted for scaling the fitness function, and then individuals are selected to genetic operations follow the roulette wheel or tournament method.

Step 3, since the individuals’ goodness differences in the blocks, mutation operator is reset respectively to each other block, like a smaller mutation probability set to individuals in the block with a high goodness and larger to low goodness, in order to ensure high population diversity.

In view of this scheme, we need to redesign fitness function and improve mutation operator.

(1) Fitness Function

On GEP-based symbolic regression problems, the two evaluation models proposed by Candida own their inherent shortcomings. In statistics, it is more usually to employ \( R^2 \) (Coefficient of Determination) to evaluate the fit degree of two sets of data. The calculation formula is as below.

\[
R^2 = 1 - \frac{SSE}{SST}
\]  

(2.1)

in which

\[
SSE = \sum_{i=1}^{n}(y_i - \hat{y}_i)^2, \quad SST = \sum_{i=1}^{n}(y_i - \overline{y})^2, \quad y_i \text{ is the real observed value, and } \overline{y}_i \text{ is the average one of observed values, and } \hat{y}_i \text{ is the regressed value. SSE is residual sum of squares of the observed values and the regressed values, and summation of SSE and SSR(regression sum of squares } \sum_{i=1}^{n}(\hat{y}_i - \overline{y})^2). \]

So, we design the fitness function like this:

\[
f = n \times 100 \times R^2 \quad (n \text{ is the sample size}) \]

(2.2)

\[
\therefore SSE < SST, \quad 0 < R^2 < 1. \text{ It can be known the range of } f \text{ is } (0, n \times 100). \quad \text{When the individual fitness of each block are very close, fitness of the next generation can hardly be improved obviously, which would lower evolutionary efficiency. So we make fitness linear amplified by multiplying the factor } n \times 100 \text{ (} n \text{ is the sample size).}
\]

(2) Mutation Operator

We set dynamic mutation probability in this paper, in order to make mutation operator self-adaptive. Mutation probability function is designed as follows.

\[
P_{im} = P_M \times e^{\frac{\overline{f}_i + e^{-C}}{\overline{f}_i - C}}
\]

(2.3)

where \( P_{im} \) is mutation probability of the current block, and \( P_M \) is a constant set before evolutionary with a range of \( (0, 0.15) \), and \( \overline{f}_i \) is average fitness of the current block and its maximum is \( (\overline{f}_i)_{\text{max}} \), while \( C = n \times 100 \) is the maximal fitness.

It can be easily learned from formula (2.3) that \( P_{im} \) of each block is in inverse ratio to the average fitness, also to generations (or \( (\overline{f}_i)_{\text{max}} \)). The value range of \( P_{im} \) is \( \left[ 0, \frac{1}{e^C} \right] \).
2.2 BS-GEP Algorithm Description

Every individual mutates on a fixed probability in the classic GEP algorithm, which affect population diversity seriously. We brought out a scheme based on block strategy to the mutation operator. BS-GEP algorithm structure is shown in Fig.1.

![Flow Chart of BS-GEP](image)

Fig.1 Flow Chart of BS-GEP

From Fig.1, it is apparently that the new algorithm adds the mutation rate reset in every generation contrast to the classic GEP.

2.3 BS-GEP Complexity Analysis

Theorem 1: the algorithm complexity is \( O(P \times G \times n) \), in which \( P \) is population size, \( G \) is the total generations, \( n \) is the sample size.

Demonstration: in the algorithm, the calculative complexity of population initialization from \( n \) samples is \( O(n) \); the fitness of each individual need to be calculated, so the calculative complexity of population fitness is \( O(P \times n) \); as the maximum of generations is \( G \), so the algorithm complexity is \( O(P \times G \times n) \).

2.4 BS-GEP Convergence Analysis

Theorem 2: the probability of convergence to the optimal solution using BS-GEP is less than 1.

Demonstration: all possible status of population is divided into two kinds, one is \( S_0 \) including the optimal individual, and another is \( S_n \) that does not have the optimal individual. \( S = S_0 \cup S_n, S_0 \cap S_n = \phi \). Wishing to demonstrate the stable probability that \( P_t \) runs to \( S_0 \) is less than 1, we take proof by contradiction: Assuming the probability is equal to 1, the probability that \( P_t \) runs to \( S_n \) is 0, that is \( \lim_{t \to \infty} P_t \in S_n = 0 \). In the process of BS-GEP evolutionary, if the population mutate from a status \( i \in S_m \) to another status \( j \in S_n \), and the mutation probability is \( m_{ij} \), the stochastic matrix \( M = [m_{ij}] \) is the population status transfer matrix of BS-GEP.

\[ M \] is a stochastic matrix, and \( m_{ij} = p_{n}^{i,j} (1 - p_{n})^{1-i,j} > 0 \) (\( H(i,j) \) is the Hamming distance between \( i \) and \( j \)), so \( M \) is positive definite. At the moment \( t \) the probability that the population is in status \( j \) is \( P_j(t) = \sum_{i \in S_m} P_i(0) \cdot m_{ij}^t, \ t = 0,1,2, \ldots \). Learning from the characteristics of the homogeneous Markov chains,[8] the stable probability distribution of \( P_j(t) \) is independent with that of initial, that is \( P_j(\infty) = P_j(\infty) m_{ij} > 0 \). At this moment \( j \in S_m \), that is to say, \( j \) is the status of \( S_m \). So \( \lim_{t \to \infty} P_t \in S_n > 0 \). This is contradictory with the previous assumption. Therefore, Theorem 2 is tenable.

It can be known from the above analysis that, the problem solving based on BS-GEP has convergence to the global optimum in probability, but not the strong convergence to the global optimum. So it can not rule out the possibility of convergence to local optimum.
3 Software Reliability Modeling Based on GEP and BS-GEP

The data series selected are the former 16 data of the software testing case in Armored force Engineering Institute, which are given in Table 1 as follows.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

where, $t_i = T_{i} - T_{i-1}, i = 1, 2, \cdots, 16$ and $T_0 = 0$ ($t_i$ is the mean time between failures (MTBF), $T_i$ is the cumulative time of failures, also means the next failure time). In this paper, we have formed GEP model and BS-GEP model just on $T_i$. Parameters of the algorithms in the test are set as shown in Table 2.

</tr>
</tbody>
</table>

(Note: To make algorithms are more suitable for software reliability modeling, in consideration of the software reliability growing characteristic, we add exponential function to $F$, which also owns growing feature. Both of the fitness maximums are 1600.)

Run the evolutionary program in the mixed environment of VC++ and Mathematica. After 1000 generations of evolution, we get preferable adaptive models and their structures expressions are as follows.

$$T_{GEP}(x) = -0.592059 + 2.67892 x^2$$
$$+ 0.386808 \left(0.203589 + x\right)$$
$$+ 0.250649 + x$$
$$- 1.54051 x(1 + x)$$
$$+ (0.559069 + x)e^{-x}$$

(3.1)

$$T_{BS-GEP}(x) = -0.162737$$
$$+ 10^{0.272627} (-0.541977 + x)$$
$$+ 10^{0.086973} x - 6.11894 + x^2$$
$$+ \left(0.037978 - x\right)(0.863582 + x)$$
$$- 0.588002 x^2 e^{-x}$$

(3.2)

3.1 The Calculation of Software Reliability Model Parameter--MTBF

The prediction of $T$ at the 17th failure by the models (3.1) and (3.2)
are \( T_{GEP} = 302.6031 \), \( T_{BS-GEP} = 300.7515 \), while the real value is 300. Accordingly, \( t(MTBF) \) at the moment \( T_{17} \) are \( MTBF_{GEP} = 41.6031 \), \( MTBF_{BS-GEP} = 39.7515 \), while 39 is the real result. In Table 3 the appraisal results on \( T_{17} \) of GEP and BS-GEP models are compared with several traditional reliability models.

<table>
<thead>
<tr>
<th>Models</th>
<th>( MTBF )</th>
<th>Next Failure Time</th>
<th>Models</th>
<th>( MTBF )</th>
<th>Next Failure Time</th>
</tr>
</thead>
<tbody>
<tr>
<td>GEP Model</td>
<td>41.6031</td>
<td>302.6031</td>
<td>G-O(NHPP)</td>
<td>50.2572</td>
<td>311.2572</td>
</tr>
<tr>
<td>BS-GEP Model</td>
<td>39.7515</td>
<td>300.7515</td>
<td>Moranda Model</td>
<td>72.4638</td>
<td>333.4638</td>
</tr>
<tr>
<td>Exponential Model</td>
<td>90.5000</td>
<td>351.5000</td>
<td>S-W Model</td>
<td>126.7990</td>
<td>342.7990</td>
</tr>
<tr>
<td>J-M Model</td>
<td>108.5019</td>
<td>369.5019</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

From the table above, we can see that the distances of \( MTBF \) and Next Failure Time values between the result by these traditional models and the real result are much larger. However, the results calculated by GEP and BS-GEP models are more suitable and accurate, and the BS-GEP model is the best. All of above can testify that the software reliability of the new models represent better than other traditional models on one-step-ahead prediction capability.

### 3.2 Failure Rate Curve

Having calculated the \( MTBF \) value, the current failure rate of the software system can be brought out by \( \lambda = 1/MTBF \). So the current reliability function is \( R(t) = e^{-\lambda t} \). By models (3.1) and (3.2) the initial failure rates are 0.86592 and 0.90668 separately, and the current failure rates at \( T=261 \) are 0.0240367 and 0.0251563 respectively. The failure rates curves of the two models are shown in Fig.2 and Fig.3.

From above figures, it is learned that the change tendency of software failure rates from the two models is similar, and tends to monotone decreasing as a whole.

### 3.3 The Short-Term Prediction Capability Comparison of Models

In order to testify the prediction capability of new models, we adopt the short-term range error (SRE) in the reference[9] for scaling the short-term prediction capability. Its formula is shown as follows.

\[
SRE = \frac{\sum_{i=1}^{n-1} |x_i (i+1) - x_p(i+1)|}{n-1} \quad (3.3)
\]

where \( x_i (i+1) \) represents the real value of next \( MTBF \) and \( x_p(i+1) \) is the next \( MTBF \) predicted by the model using the former \( i \) failure data. The smaller the SRE value is, the stronger and better models' short-term prediction capability will be, meanwhile, the more accurate the one-step-ahead prediction capability will be gotten.
In the view of our testing case above, we can get the prediction results of failure data series from the 13th point to the 17th one, which are calculated by the seven models above. Their calculated results and the SRE values are given in Table 4.

<table>
<thead>
<tr>
<th>Prediction Results</th>
<th>Exponential Model</th>
<th>J-M</th>
<th>G-O(NHPP)</th>
<th>Moranda</th>
<th>S-W</th>
<th>GEP</th>
<th>BS-GEP</th>
</tr>
</thead>
<tbody>
<tr>
<td>The 13th point</td>
<td>50.0833</td>
<td>211.1405</td>
<td>34.7047</td>
<td>37.8788</td>
<td>78.5848</td>
<td>30.1566</td>
<td>26.0533</td>
</tr>
<tr>
<td>The 14th point</td>
<td>58.1540</td>
<td>84.0211</td>
<td>28.6110</td>
<td>30.3030</td>
<td>38.3494</td>
<td>46.3531</td>
<td>42.0821</td>
</tr>
<tr>
<td>The 15th point</td>
<td>66.6430</td>
<td>70.0565</td>
<td>30.2247</td>
<td>37.0370</td>
<td>48.1770</td>
<td>55.8263</td>
<td>51.7706</td>
</tr>
<tr>
<td>The 16th point</td>
<td>79.1330</td>
<td>81.5659</td>
<td>75.1856</td>
<td>55.8659</td>
<td>124.0762</td>
<td>12.5763</td>
<td>9.26688</td>
</tr>
<tr>
<td>The 17th point</td>
<td>90.5000</td>
<td>108.5000</td>
<td>50.2572</td>
<td>72.4638</td>
<td>126.7990</td>
<td>41.6031</td>
<td>39.7515</td>
</tr>
<tr>
<td>SRE</td>
<td>2.3520</td>
<td>3.1275</td>
<td>2.5214</td>
<td>2.2198</td>
<td>5.0278</td>
<td>0.7130</td>
<td>0.5175</td>
</tr>
</tbody>
</table>

Comparing with these short-term prediction results and the SRE values, we can draw the conclusion that $SRE_{BS-GEP} < SRE_{GEP} < SRE_{Moranda} < SRE_{ExponentialModel} < SRE_{G-O} < SRE_{J-M} < SRE_{GEP}$. It is these values that prove the short-term prediction capability of new models much more superior to others. So their predictive effectiveness is testified.

### 3.4 Model Simulation

Fig.4 and Fig.5 give out the cumulative time simulation figures of the two models.

Both GEP and BS-GEP models fit failure data quite well. GEP executes to the 900th generation when program finds the optimal solution, and the fitness is 1182.285551 and the time-consume is 10.5 seconds. But to BS-GEP, the optimal one is found just at the 350th generation with fitness value of 1576.162104, and it only takes 3 seconds. It is very clear that the BS-GEP model has a higher predictive efficiency and can fit better than GEP. (Fitness represents error between the predictive value and the real one.)

In addition, we have created the reliability model with software MTBF series, as well as the error statistical data of NTDS (Naval Tactical Data System) of America Navy tactical systems as well as the error statistical accumulative failure data series of SYS1、SYS2、SYS3[5] from Musa in 1979. We also analyzed and appraised some criteria, which can all testify the applicability of BS-GEP. All what we have done have testified the feasibility and availability of this algorithm on both theory and applications.

### 4 Conclusions

GEP has strong data mining capacity. The new reliability model constructed with BS-GEP algorithm...
has excellent prediction accuracy and goodness of fit. The algorithm complexity and convergence of BS-GEP is analyzed in the paper. Having experimented on several cases, we can find that BS-GEP model is better than the classic GEP model, as well as the several other traditional probability models, also faster than GEP on speed of solving. The new method is proved widely used for many other time sequences and has a wider versatility.
